1 Optimised draining of valves

In specialist literature and documents from valve manufacturers and plant constructors the term "self-draining" is often used in conjunction with valves and plants or plant sections. This term is to describe the residue-free and independent emptying of vessels and pipes through an opened valve. This draining depends on various factors. Even a vertical pipeline with open ends does not guarantee complete and residue-free draining.

The terms "free/unhindered outlet" or "optimised draining" is more realistic.

Optimum drainability of a valve depends on several factors:

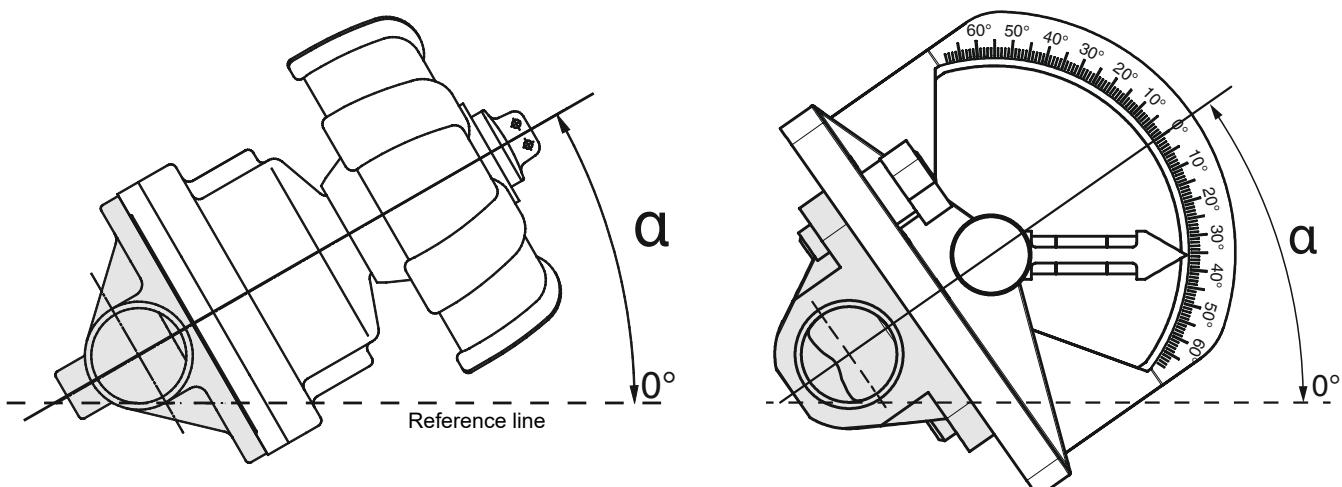

- Design of the internal geometry of the valve body
- Nominal pipe size
- Pipe standard (DIN, ISO, ASME BPE, etc.), as they have different inside diameters at the same nominal size
- Surface finish (topography, morphology and adhesive quality of the media wetted surfaces)
- Installation angle in the pipeline and valves with regard to horizontal rotation and angle of rotation of the valves
- Viscosity of medium

The angles of rotation given in the tables were calculated. Exact compliance is difficult to achieve when installing valves. A tolerance range of +/- 2° can be assumed as a rule of thumb for optimised emptying of the valves.

The residue-free drainability and emptying of a plant and its components is nevertheless the responsibility of the plant designer, constructor and operator and is essentially dependent on the design and layout of the plant.

2 Calculated angles of rotation for installation in horizontal pipelines

GEMÜ has calculated angles of rotation for the various nominal sizes and pipe standards in order to facilitate installation of valves for optimised draining. The angles of rotation α mentioned are valid for installation in horizontal pipe systems. Please note the drawing. (Attention: Other manufacturers quote the angle using a horizontal weirplate from the vertical centreline downwards). Angle of rotation for block material bodies (e.g. made of special material) on request.
